CS583

When I started developing my game I noticed the game I described in my one pager was a lot more complex than I initially thought. This made me cut out some of the things I wanted in my game and shift the overall gameloop. The main idea of my game is there, which is essentially a minion wave clear game where your character is supposed to defeat waves of creeps in order to advance to the next level. The main thing that changed was the “farm” and shop idea I had that took inspiration from MOBAs. I realized both the implementation and balancing would have taken too long so I decided to completely change this by adding the shop in between levels. Instead of gaining money from every minion defeated, the player gets one of three upgrades every time he defeats a wave. With this I also decided to remove the “base” and just make the characters life the main objective you should protect in the game. Ultimately, the game loop changed from the player deciding what to upgrade and if getting extra minions is worth the damage his base will take while he leaves, to a more classic wave clear game where you have to defeat the level to move on to the next one. Although many things were scrapped from my original idea, I was still able to implement a lot of the things I wanted to have in the game thanks to the help I could get from an AI. Before this class I had never done any game development before and most of the concepts seen were new to me. Using AI helped me implement some of the things I would not have known how to, as well as explained to me how they worked. Some examples are how the game is able to get my cursor position in order to aim the weapon towards it or how to handle my weapon animations so that bullets don't travel through enemies. With this assistance I was able to produce a much better game as well as learn and implement new things that I did not know before and were not seen in class.
